

DriveLegal — NZTA Reporting Specification

Reporting, data capture, compliance calculation, PDF and Excel consistency

1. Purpose

This specification defines the reporting requirements identified from the supplied LogNinja and DriveLegal records. The objective is to make DriveLegal reports clear, auditable, consistent, and suitable for review in an NZTA compliance context. The specification focuses on correct data capture and calculation rather than copying the visual layout of LogNinja.

2. Single source of truth

PDF and Excel reports must be generated from the same underlying event data and the same compliance calculation engine. The two outputs must not independently recalculate or transform the data. For the same report period, driver, and records, the PDF and Excel must contain exactly the same dates, times, durations, registrations, work/rest events, calculations, and compliance results.

3. Header requirements

Include	Requirement
Driver name	Show the driver associated with the report.
Licence / driver identifier	Show the applicable identifier used by DriveLegal.
TCL number	Include the TCL number in the report header.
Report date / date range	Show the reporting period clearly.
Vehicle registration	Use the correct registration associated with the relevant event/vehicle.
Vehicle type	REMOVE from the header and from the report where it is not reliable compliance data.

4. Vehicle data capture

Vehicle registration must be captured from the actual vehicle associated with each relevant event. The system must not carry a stale registration across vehicle changes. If the driver changes from a passenger vehicle to a large vehicle, the subsequent records must show the new vehicle registration. Vehicle type must not be hard-coded or inherited from a previous vehicle.

The supplied DriveLegal report currently shows the same registration (REL10) and the vehicle type 'Hatchback' across its rows. This was identified as a reporting concern because the vehicle may change. The supplied record therefore supports the requirement to correct vehicle association and remove the unreliable vehicle-type field. ■filecite■turn0file1■L4-L17■

5. Raw event capture

The report must preserve an auditable event timeline. Each event should retain its original timestamp, event type, vehicle registration, and relevant location or other captured metadata. The raw event record must remain distinguishable from calculated compliance values.

The supplied LogNinja record demonstrates the type of event-level information that needs to remain traceable, including WORK and REST events with timestamps and vehicle registration REL10. ■filecite■turn0file0■L19-L50■

6. Work/rest calculation

- Calculate work periods from the captured event sequence, not from a simplified daily summary.
- Clearly identify the start and end of each work period and the rest periods that interrupt it.
- Where a work period crosses midnight, retain the actual continuous event and clearly show how it is allocated to the applicable compliance period.
- Every calculated duration must be reproducible from the underlying timestamps.

- Every breach must identify the rule applied and the measured duration that caused the breach.

7. Compliance result presentation

For each relevant work period or reporting row, show the compliance result and enough information for a reviewer to reproduce the result. A breach should be expressed plainly, for example: rule limit, actual duration, and amount by which the limit was exceeded.

8. PDF and Excel must match exactly

Data element	PDF vs Excel
Driver	Must match exactly
TCL number	Must match exactly
Date / time	Must match exactly
Event type	Must match exactly
Work/rest duration	Must match exactly
Vehicle registration	Must match exactly for each applicable event
Compliance rule	Must match exactly
Compliant / breach result	Must match exactly
Calculated totals	Must match exactly

9. Current records — items requiring attention

The supplied DriveLegal report contains rows marked both Compliant and Breach, with work, break, and distance values. For example, it records 10 August as a breach with 11h 50m work, 11 August as compliant with 5h 23m work, and 12 August as a breach with 10h 20m work. These values need to be traceable back to the underlying event sequence. ■filecite■turn0file1■L9-L17■

The supplied LogNinja record also shows a work event beginning at 12:02 on 11 August and ending with a REST event at 06:11 on 12 August, with warnings that the work event exceeded 14 hours, 13 hours, and 7 hours. This illustrates why cross-midnight event handling must be explicit and auditable. ■filecite■turn0file0■L83-L103■

10. Acceptance criteria

- No vehicle type appears in the report header.
- Vehicle type is not used as a hard-coded value for different vehicles.
- The correct vehicle registration is captured and displayed for each applicable event.
- TCL number is present in the header.
- Raw event timestamps are preserved.
- Work/rest calculations can be reproduced from raw events.
- Cross-midnight work periods are handled consistently.
- Every breach identifies the applicable rule and supporting duration.
- PDF and Excel are generated from the same source data and calculation results.
- A comparison of PDF and Excel for the same report produces no data differences.

Important: This document is a product/reporting specification based on the supplied records and the requirements discussed. It does not by itself constitute NZTA approval or a legal determination of compliance. Final compliance logic should be validated against the applicable NZTA requirements before release.
